

# The Debian T<sub>E</sub>X sub-policy

The Debian teT<sub>E</sub>X mailing List <debian-tetex-maint@lists.debian.org>

generated from \$Id: Debian-T<sub>E</sub>X-Policy.sgml 1564 2006-08-15 11:28:32Z frank \$

## **Abstract**

This document provides a set of rules for the packaging of applications, fonts and input files related to T<sub>E</sub>X within the Debian GNU/Linux distribution.

# About this document

This document provides a set of rules for the packaging of applications, fonts and input files related to  $\text{\TeX}$  within the Debian GNU/Linux distribution. It is still a in a draft state – some things might not yet be fully implemented, and others are advisable, but not strictly necessary. If in doubt, please ask on `debian-tetex-maint@lists.debian.org`.

The latest copy of this document can be found in the `Debian-TeX-policy` files in the `tex-common` package.

## Chapter 2

# Terms and Definitions

The following terms are used in this document:

**T<sub>E</sub>X-related package** Any Debian package that uses or provides parts of the T<sub>E</sub>X infrastructure, i.e. the T<sub>E</sub>X or METAFONT program or derivatives thereof, fonts or input files in a *TEXMF* tree, etc.

**tex-common** This package provides basic infrastructure and some configuration files for all T<sub>E</sub>X-related packages, including the `configuration update` programs.

**Basic T<sub>E</sub>X packages** A Basic T<sub>E</sub>X package is a Debian package that provides the basic infrastructure for T<sub>E</sub>X-related programs. It should provide sufficient functionality for typesetting most generated (La)T<sub>E</sub>X code, e.g. from docbook, debiandoc, or texinfo sources. Usually, the Basic T<sub>E</sub>X packages will be divided into an architecture-dependent and an architecture-independent package.

The arch-dependent package must provide at least one binary that is fully compatible with Donald E. Knuth's original T<sub>E</sub>X program, and it should provide the original T<sub>E</sub>X itself. The output formats `dvi`, PostScript and Adobe PDF must be available, either directly or by conversion of other output formats. The arch-independent package must provide at least the files necessary to create the formats for plain T<sub>E</sub>X and L<sup>A</sup>T<sub>E</sub>X and the input files required by the L<sup>A</sup>T<sub>E</sub>X distribution, as well as the Computer Modern fonts.

**TDS** The T<sub>E</sub>X Directory Structure, which describes file placement for T<sub>E</sub>X input files. The latest version of the TDS is available at <http://www.tug.org/twg/tds/>.

**TEXMF tree** One directory tree, arranged according to the TDS

**T<sub>E</sub>X input file** A file that is meant to be used by a T<sub>E</sub>X-related program; technically any file that can be found by the `/kpathsea/kpse` library. This includes e.g. Type1 font files.

**configuration update programs** The configuration information from files provided by different T<sub>E</sub>X-related packages must be merged and made available in appropriate form to the various programs. This is usually done by scripts that write files into the *TEXMFSYSVAR* tree.

---

Currently, the configuration update programs provided by `tex-common` are:  
`update-texmf`, `update-fmtutil`, `update-language`, `update-updmap`.

## Chapter 3

# File Placement

This chapter describes the placement of  $\TeX$  input files, so that they can be found by programs. Files that are not  $\TeX$  input files must not be put in a  $\text{TEXMF}$  tree (put them into `/usr/share/package` instead). As an exception, documentation files in plain text may be used inside a  $\text{TEXMF}$  tree, e.g. to explain the purpose of an otherwise empty directory.

### 3.1 Path searching and `libkpathsea` / `libkpse`

The Basic  $\TeX$  packages must provide a mechanism for searching through  $\text{TEXMF}$  trees that allows different files to be found depending on the invoking program and the specified file format. The only existing implementation is the `libkpathsea` library. Unfortunately, it was not originally designed for use as a dynamic shared library. A rewrite is under way to create a `libkpse` library with proper API specification and ABI compatibility. For the time being, the Basic  $\TeX$  packages can provide a shared library, and program maintainers can decide to use it, or to link statically against their own copy of the code.

For use in scripts, the Basic  $\TeX$  packages provide the utilities `kpsewhich`, `kpsepath`, `kpsexpand`, and `kpsestat`.

### 3.2 Directory trees

File locations must follow the  $\TeX$  Directory Structure, TDS. It is a bug if a package only conforms to an outdated TDS version. It is a more severe bug, however, if it conforms to the current TDS version but does not make sure to depend on an appropriately recent version of the Basic  $\TeX$  packages or `tex-common` (that support this TDS version).

The following  $\text{TEXMF}$  trees are defined, as outlined below:

- 1 `/usr/share/texmf-tetex/`, part of  $\text{TEXMF}$ *DIST*
- 2 `/usr/share/texmf-texlive/`, part of  $\text{TEXMF}$ *DIST*

- 3 `/usr/share/texmf/`, referenced as *TEXMFMAIN*
- 4 `/var/lib/texmf/`, referenced as *TEXMFSYSVAR*
- 5 `/etc/texmf/`, referenced as *TEXMFSYSCONFIG*
- 6 `/usr/local/share/texmf/`, referenced as *TEXMFLOCAL*
- 7 Any directories listed in the *TEXMFHOME* configuration variable in `texmf.cnf` or as an environment variable,
- 8 optionally user-specific directories for configuration files (*TEXMFCONFIG*) and generated files (*TEXMFVAR*)

The search order is from bottom up (files in *TEXMFHOME* taking precedence over files in *TEXMFMAIN*) *etc.*

The role of the trees *TEXMFMAIN* and *TEXMFDIST* in Debian differ from upstream's original usage. Upstream uses *TEXMFMAIN* for the files that have to match the binary executables and *TEXMFDIST* for other T<sub>E</sub>X input files that are replaced when a new `texmf` tarball appears; this distinction is not necessary on a system with a decent package management system. Instead, the basic T<sub>E</sub>X packages install their files into their *TEXMFDIST* directories<sup>1</sup>, while *TEXMFMAIN* is used by T<sub>E</sub>X add-on packages for their files and allows them to shadow older versions provided by the basic T<sub>E</sub>X packages. A couple of files from the basic T<sub>E</sub>X packages still need to be placed in *TEXMFMAIN*<sup>2</sup>.

The order of basic T<sub>E</sub>X packages in *TEXMFDIST* may be changed by the user or by the basic T<sub>E</sub>X packages, and no implementation may rely on a particular order. This implies that for a package that needs a version of a particular file newer than provided by one of the basic T<sub>E</sub>X packages, it is not sufficient to declare a dependency on the other basic T<sub>E</sub>X package(s)<sup>3</sup>.

Debian packages generally install files in *TEXMFMAIN*, and may ship or create empty directories in the other trees, in accordance with Debian Policy. Configuration file handling in *TEXMFSYSCONFIG* is described below in 'Configuration files' on page 9. Packages should take care to ignore *TEXMFHOME* in their maintainer scripts.

### 3.3 Generated files

Generated files should be created below *TEXMFSYSVAR* (or the user-specific variable directories, *TEXMFVAR*), with the subdirectory structure conforming to the TDS. Generated font files will either be created in each user's *TEXMFVAR* tree, or in the *VARTEXTENTS* tree<sup>4</sup>

---

<sup>1</sup>This is new, and the basic T<sub>E</sub>X packages currently transition their files to the new place.

<sup>2</sup>Reasons include hardcoded paths in executables as well as the need for e.g. pool files to exactly match the binaries' version, so that shadowing must be prevented.

<sup>3</sup>Of course this is only a problem if the file is needed in the configure phase. If it is needed only at runtime, a README file to instruct the local admin should be sufficient.

<sup>4</sup>Per default, this tree is located in the world-writable directory `/tmp/texfonts/`, in order to allow automatic package builds to work without user directories. On multi user systems, the admin might want to change this to a persistent directory and set up proper permissions

An exception is the generated file `/etc/texmf/texmf.cnf`. It is not intended that local administrators edit that file, but if they do, the configuration update programs must respect these changes. Debian packages must not alter that file.

### 3.4 Filenames and installation of alternative files

Packages may not install files with the same name as a file already installed in a *TEXMF* tree, unless both files are in subdirectories where they will only be found by different applications, as determined by the `--prognam` or `--format` switches to `kpsewhich`.

There are two exception to this rule:

- 1 Basic  $\text{\TeX}$  packages install their files into their *TEXMFDIST* directory and will usually contain files that are also in other basic  $\text{\TeX}$  packages.
- 2 Packages that need newer versions of a file than already supplied by a basic  $\text{\TeX}$  package and installed in *TEXMFDIST* can place them into *TEXMFMAIN*. Thus, the outdated file will be shadowed, and the new one is in effect.

The maintainer of the basic  $\text{\TeX}$  package should be made aware of the problem <sup>5</sup> The package maintainer must make sure to follow new releases of the basic  $\text{\TeX}$  packages and not continue shadowing a file that is newer than the version provided by the shadowing package.

The package must make sure that the newer version is backward-compatible, meaning it must not break compilation of any  $\text{\TeX}$  document, and it should not change the output file. A change of the output file may be acceptable if an obviously buggy behavior is corrected, **and** if it had previously not been possible to easily fix this behavior in user's documents (or if the updated package and a possible fix in the document combined lead to a correct document).

Installing more than two versions of a file will most likely lead to confusion. Therefore, the possibility to shadow a file once should be enough, and the usage of `dpkg-divert` is discouraged.

It is also discouraged to use a file other than from the canonical source for that file, usually the CTAN network.

### 3.5 Documentation

Packages should make documentation available to `texdoc`. This can be done by either installing the files below `/usr/share/doc/texmf`, or by providing symlinks from subdirectories of that location to the actual documentation files. To allow partial parallel installation of

---

<sup>5</sup>A wishlist bug on the shadowing package, blocked by an other wishlist bug on the basic  $\text{\TeX}$  package, can help tracking these issues.

different basic T<sub>E</sub>X packages, these always install their documentation files into `/usr/share/doc/packagename` and put symlinks into their respective *TEXMF**DIST*.

A package must not install files into (subdirectories of) `/usr/share/texmf/doc`, which is a symbolic link to `/usr/share/doc/texmf`.

The entry points for documentation should have names that indicate what they document. Names like `manual.pdf` or `index.html` should be avoided, even if the directory name is unmistakable<sup>6</sup>.

---

<sup>6</sup>This allows users to say `texdoc packagename` directly. Otherwise they will first have to find the right command line (e.g. `texdoc packagename/user.dvi`) using `texdoc -s keyword`

## Chapter 4

# Configuration

### 4.1 Configuration files

Files that are used to modify the behavior of executables must be treated as any other configuration file in a Debian package. However, files that are used to control the typeset output - the appearance of documents - need not be treated as configuration files. It is up to the maintainer of the package to decide which files make sense to be used for site-wide (as opposed to per-project or per-document) customization.

A typical case for a site-wide configuration file is a file that must be changed if a style file should use additional modules (installed, for example, into TEXMFLOCAL). Options that only control document output are rather used for a particular document or documentation project and should usually not be installed as a configuration file.

Note that `/etc/texmf/` is a usual TDS tree. Files can be put into appropriate TDS-conforming subdirectories (e.g. `/etc/texmf/fonts/map/`), but directories not specified in TDS (or added Debian-specifically in `tex-common`'s files in `/etc/texmf/texmf.d/`) are generally not searched for  $\TeX$  input files and can be used by packages for configuration files that are not  $\TeX$  input files (e.g. the files in subdirectories `fmt.d` or `updmap.d`).

### 4.2 Configuration update programs

The central configuration file for  $\TeX$  applications is `/etc/texmf/texmf.cnf`, the central font configuration file is `/var/lib/texmf/web2c/updmap.cfg`, the central language/hyphenation configuration `/var/lib/texmf/tex/generic/config/language.dat`, and format generation is determined by `/var/lib/texmf/web2c/fmtutil.cnf`. All four files are generated by configuration update programs from configuration files in subdirectories of `/etc/texmf`. For `updmap.cfg`, `language.dat` and `fmtutil.cnf`, this is the only method of configuration. `texmf.cnf` can be edited manually by local system administrators, and changes will be handled by `ucf`. Package installation scripts, however, must not change this file, but use the `update-texmf` mechanism. Local administrators are encouraged to use the `update-texmf` mechanism, too.

Packages are free to add configuration items to the common configuration files, but they should not try to override configuration items that are supplied by other packages. Rather, shared configuration items should be supplied by the Basic T<sub>E</sub>X packages or any other package on which all involved packages depend, with a setting appropriate for all. If this is impractical, the involved packages must at least agree on the way different packages override other's settings<sup>1</sup>.

Maintainer scripts should call `update-updmap` with the option `--quiet`. Besides that, the configuration update programs should be called without any options to allow for internal changes, e.g. of the directories where the generated files are placed.

Packages that changed `updmap.cfg` must call `updmap-sys` as detailed in 'Font configuration' on the current page. Packages that changed `language.dat` or `fmtutil.cnf` must call `fmtutil-sys` (see below). They must make sure to issue the `mktexlsr` command before this.

### 4.2.1 Font configuration

A package that provides PostScript Type 1 fonts for T<sub>E</sub>X should be usable with any Basic T<sub>E</sub>X Package. The recommended way to implement the configuration scheme described below is to use the debhelper program `dh_installtex` provided by `tex-common`. See `dh_installtex(1)` for usage details.

For the rest of this section, we'll assume we are dealing with a package named *package* that installs PostScript Type 1 fonts for T<sub>E</sub>X. *package* should fulfill the following requirements:

- 1 It should depend on `tex-common` but not on any Basic T<sub>E</sub>X Package, unless needed for another task than simply installing the fonts for T<sub>E</sub>X.
- 2 It should install the necessary map files (`.map` extension) below `TEXMFMAIN/fonts/map`. The precise location must conform to TDS version 1.1.
- 3 It should also obviously install other needed or useful files provided by upstream to use the fonts with T<sub>E</sub>X-related programs (`.pfb`, `.tfm`, `.enc`, `.fd`, `.sty`, documentation, etc.).
- 4 It should install one or more configuration files with names following the pattern `10name.cfg` into `/etc/texmf/updmap.d/`. Such files will be later merged by `update-updmap` to form `/var/lib/texmf/web2c/updmap.cfg`, the effective configuration file for `updmap-sys`.

Exactly what to put in these files is documented in `update-updmap(1)`. Basically, they should contain the pseudo-comment:

```
# __- DebPkgProvidedMaps __-
```

---

<sup>1</sup>Note that in `texmf.cnf`, as well as in the sequence of multiple `texmf.cnf` files that are read, earlier entries override later ones.

as well as the usual `Map` and/or `MixedMap` lines that *package* needs to add to `/var/lib/texmf/web2c/updmap.cfg`.

- 5 It should install a file named `/var/lib/tex-common/fontmap-cfg/package.list` that contains a reference to every `.cfg` file from the previous step, one per line. For instance, if *package* installs `10foo.cfg` and `10bar.cfg` into `/etc/texmf/updmap.d/`, the contents of `/var/lib/tex-common/fontmap-cfg/package.list` should be:

```
10foo
10bar
```

This `package.list` file must be shipped in the `.deb`, so that when *package* is removed (not necessarily purged), `package.list` disappears from `/var/lib/tex-common/fontmap-cfg/`.

- 6 It should run:
  - in `package.postinst`;
  - when `package.postrm` is called with `remove` or `disappear` as its first argument the following commands in this order: `update-updmap --quiet`, `mktexlsr` and `updmap-sys`.

Since `mktexlsr` and `updmap-sys` are provided by the Basic T<sub>E</sub>X Packages, `package.postinst` has to ensure that they are only called when found in `$PATH` (unless *package* depends on the Basic T<sub>E</sub>X Packages for some reason). In `package.postrm`, the same considerations must be taken into account, with the addition that `tex-common` (that provides `update-updmap`) can be unconfigured or even uninstalled.

Note that even when `tex-common` is configured, it cannot be assumed that `update-updmap`, `mktexlsr` and `updmap-sys` can be safely run whenever available, because they internally use `kpsewhich` which only works after the `libkpathsea` library in a separate package has been configured properly.<sup>2</sup> The following check can be used to determine whether `libkpathsea` is configured:

```
if kpsewhich --version >/dev/null 2>&1; then
    echo "kpsewhich is installed and libkpathsea is configured."
else
    echo "Either kpsewhich is not installed, or libkpathsea is not confi
fi
```

A sample implementation of this scheme can be found in ‘Sample code for font packages’ on page 17, but the recommended way to implement this scheme is to use `dh_installtex`.

The rest of this section explains the rationale behind the previous recommendations.

---

<sup>2</sup>However, `update-updmap` uses `libkpathsea` only in `user-specific-mode`. In `system-wide mode`, it doesn’t matter whether `libkpathsea` is configured or not.

- The dependency on `tex-common` ensures that in `package.postinst`, `update-updmap` can be run and `texmf.cnf` is in a sane state, so that `mktexlsr` and `updmap-sys` can be run safely (if present and if `libkpathsea` is configured).
- The recommended order for running the programs `update-updmap`, `mktexlsr` and `updmap-sys` ensures that `updmap-sys` can locate the newly-installed files (in particular, the map files shipped by *package*), since `mktexlsr` is run before `updmap-sys`. It is also run after `update-updmap`, because `/var/lib/texmf/web2c/updmap.cfg` might have been created by `update-updmap`, although it more probably already existed. And since it would be of no use to call `mktexlsr` before `update-updmap`, we recommend to run it after, just in case.
- Now, about the “magic comments” in `/etc/texmf/updmap.d/*.cfg` and the `package.list` file in `/var/lib/tex-common/fontmap-cfg/`. When that *package* is removed, but not purged, it has to make sure that its `update-updmap` configuration files in `/etc/texmf/updmap.d/` are ignored. Otherwise, any call to `updmap-sys` by an other package or the local admin would fail because it cannot find *package*’s map files. Besides, we want the `/etc/texmf/updmap.d/*.cfg` files to be conffiles (unless we really have no other choice), because then `dpkg` automatically handles upgrades while preserving user modifications for them. As a consequence, moving the `.cfg` files from *package* out of the way when it is removed is not an option. Moreover, the user would wonder where his configuration files have gone in such a case.

The solution we chose was to add a little bit of logic into `update-updmap`, so that whenever it sees a `.cfg` file (let’s call it `10foo.cfg`) that has the “magic comment”, it actually includes its contents into `updmap.cfg` if, and only if:

- it is up-to-date (which is assumed if `10foo.cfg.dpkg-new` doesn’t exist in the same directory);
- `10foo` appears on a line by itself in one of the `.list` files in `/var/lib/tex-common/fontmap-cfg/`.

Additionally, that `.list` file should be named `package.list` if `10foo.cfg` comes from *package*, for simple reasons of tidiness.

With this little mechanism in place, all the rest follows as expected:

- When *package* is removed, but not purged, `package.list` is first removed by `dpkg` from `/var/lib/tex-common/fontmap-cfg/`, thus disabling the the `.cfg` files shipped by *package* as far as `update-updmap` is concerned. Then, `package.postrm` calls `update-updmap`, `mktexlsr` and `updmap-sys`, with the result that *package*’s map files aren’t listed anymore in the final map files (`psfonts.map`, `pdftex.map`...) generated by `updmap-sys`.
- If *package* is reinstalled later, two files are first created by `dpkg` during the unpack phase: `/var/lib/tex-common/fontmap-cfg/package.list` and `/etc/texmf/updmap.d/10foo.cfg.dpkg-new`. As long as the second one exists, the conffile `/etc/texmf/updmap.d/10foo.cfg` will be ignored by

update-updmap<sup>3</sup> because it may be outdated. Eventually, *package* is configured; *package.postinst* runs `update-updmap`, `mktexlsr` and `updmap-sys`, and the `.cfg` files shipped by *package* aren't ignored by `update-updmap` this time, since they are referenced in `/var/lib/tex-common/fontmap-cfg/package.list` and the `.dpkg-new` files don't exist anymore. Thus, the map files shipped by *package* do end up in the final map files generated by `updmap-sys`.

## 4.2.2 Language/Hyphenation configuration

A package that provides additional hyphenation patterns for  $\TeX$  should be usable with any Basic  $\TeX$  Package. The recommended way to implement the configuration scheme described below is to use the debhelper program `dh_installtex` provided by `tex-common`. See `dh_installtex(1)` for usage details.

These packages should put the actual hyphenation file into the respective places in *TEXMF-MAIN*, and have them registered by putting a configuration file with extension `.cnf` into `/etc/texmf/language.d` and calling `update-language`. The file contents will then be incorporated into `/var/lib/texmf/tex/generic/config/language.dat`, the effective configuration file for  $\TeX$  and friends' hyphenations.

Hyphenation patterns present the same problem as described in the previous section for font configuration files: If the package is removed, but not purged, the patterns are deleted, but the configuration information is still in `/etc/texmf/language.d/`, and the format generation would fail if they would be included in `language.dat`. Therefore, an analogous mechanism has been implemented as described for `update-updmap`: If a file in `/etc/texmf/language.d/` contains the "magic comment"

```
# -- DebPkgProvidedMaps --
```

it will only be used as long it is:

- up-to-date (which is assumed if the same file with `.dpkg-new` suffix doesn't exist in the same directory);
- listed in a file in `/var/lib/tex-common/language-cnf/` which should have the name `package.list`.

Calling `update-language` is *\*not\** sufficient to be able to use the new hyphenation patterns; instead the formats that use it need to be regenerated. This can be done by running `fmtutil-sys --byhyphen `kpsewhich --progrname=latex language.dat``.

If a package that provides additional hyphenation patterns is removed, it must make sure the formats are properly recreated without it. With the "magic comment" mechanism, this means to run `update-language` and `fmtutil-sys --byhyphen `kpsewhich --progrname=latex language.dat`` in `postrm`

<sup>3</sup>An `update-updmap` call could take place if another package such as `tetex-bin` is configured in the meantime. That happens sometimes with APT.

There is currently no mechanism (i.e., no `update-language`) for automatic addition of hyphenation patterns to formats that do not use the same hyphenation configuration file as  $\text{\LaTeX}$ .

The recommended way for implementing this scheme is to use `dh_installtex`.

### 4.2.3 Format configuration

As with font map configuration and language hyphenation patterns configuration, packages that provide additional formats should be usable with any Basic  $\text{\TeX}$  Package. The recommended way to implement the configuration scheme described below is to use the debhelper program `dh_installtex` provided by `tex-common`. See `dh_installtex(1)` for usage details.

These packages should put a configuration file according to `fmtutil.cnf(5)` into `/etc/texmf/fmt.d/`, run `update-fmtutil` and subsequently create the format with `fmtutil-sys --byfmt format`. `fmtutil-sys` will only try to create the format if it can find the corresponding `format.ini` file (the last argument in an `fmtutil.cnf` line). Therefore the `format.ini` file should not be a conffile.

If a package needs to create formats at runtime, it should use a local `fmtutil.cnf` with the appropriate entries and specify its location to `fmtutil` on the command line, using the `--cnffile` switch.

Upon package removal, `update-fmtutil` must be called in `postrm`, and the created formats and log files should be removed from the directory specified by ``kpsewhich -var-value=TEXMFSYSVAR`/web2c`.

The recommended way for implementing this scheme is to use `dh_installtex`.

## 4.3 Best practices for packages that build-depend on the $\text{\TeX}$ system:

If packages that build-depend on the  $\text{\TeX}$  system need a changed configuration, they should not try to provide it statically. If settings in any other configuration file are inappropriate for a package to build, this is (usually) a bug in the package that provides the file. It should be fixed in this package, not circumvented by a workaround in the build process. Such workarounds have proven to be problematic, because they might stop working after changes in the depended-on package, and such failure cannot be foreseen by its maintainers. If a change is still necessary, the package should use the configuration update programs with the `--outputdir` and `--add-file` options.

## 4.4 Command execution and format files

If  $\text{\TeX}$  formats need to be generated before execution, this should be done in the post-installation script. Packages that depend on an executable can thus simply declare `Depends:`

on the package providing the executable, and *only* do that. Any additional checks, e.g. for the existence of format files, is unnecessary and harmful, causing internal changes (e.g. of format file extensions) to break the depending package that does this check. Maintainer scripts or programs in Debian packages should always use `fmtutil` or `fmtutil-sys` for format generation, and either add a `fmtutil.cnf` snippet in `/etc/texmf/fmt.d/` (with `fmtutil-sys`, for site-wide formats), or use `fmtutil` with the `--cnffile` option and an appropriate local `fmtutil.cnf` (for runtime programs)

Local administrators can override settings from `texmf.cnf` with environment variables; this has sometimes lead to errors in `postinst` scripts. It is recommended that `postinst` scripts unset relevant variables before format creation or other problematic tasks.

## 4.5 The Dpkg Post-Invoke Mechanism

This section was intended to deal with a once-planned mechanism that would allow to delay running of `mktextlsr`, `updmap` and perhaps even “`fmtutil -all`” until all  $\text{\TeX}$ -related packages that want to do this are configured. Thus, it would be unnecessary to call the programs multiple times. Coding this is not hard, however it is unclear how it could be made sure that failures get attributed to the correct package. Therefore this plan has been dropped.

## Appendix A

# Sample code

This section contains sample code that implements the recommendations of this document.

### A.1 Sample code for font packages

Sample postinst script:

```
#
# postinst-texfonts
#
# postinst snippet for installing Type 1 fonts for TEX
#
# Author: Florent Rougon <f.rougon@free.fr>
#
update_fontmaps()
{
    update-updmap --quiet
    # All of the following needs an installed and configured
    # basic TEX system, so check this.
